

## CMSC 143: Introduction to Object-Oriented Programming with Robots

# Lab 8: Photobooth

## Due November 1, 2010

Submit a copy of your python program named `cmssc143_lab8_NAME.py`. You should include a sample image named `test.jpg`. You should have your name, email, and the date at the top of the file as a comment.

### Learning Objectives

- Manipulate Images.
- Understand Image Coordinate Systems
- Use Nested Loops.

### Functions to be Implemented

You should implement the first five functions, and choose one of the functions 6–9. All your functions should return a **new** image, i.e. they should not modify the original. Your file should look something like:

```
def mirror(image):  
    INSERT CODE HERE  
  
if __name__ == "__main__":  
    p = makePicture("test.jpg")  
    show(p, "original")  
    show(mirror(p), "mirrored")  
    show(flip(p), "flipped")
```

1. `mirror(image)` – Create a mirror image (reversed horizontally)

2. `flip(image)` – Create an upside-down image

3. `resize(image, factor)` – Resize the image according to factor; a factor of 2 should make it twice as big, a factor of 0.5 should make it half its original size.

4. `photobooth(listOfImages)` – Write a function that takes a list of images and creates a new image with all the images appended vertically, like the photobooths of years past.

5. Create a program that uses your scribbler's camera to create a photobooth. The scribbler should take 5 pictures, around 2 seconds apart. You might want to beep before taking the image, so your user can smile or make a goofy face. Feel free to apply one of your special effect functions to the images. Then use your `photobooth()` function to create one big image, and save it to a file.

## PICK ONE

6. `nest(image)` – Write a function that uses `resize` to nest an image inside of itself, recursively. (Although, your function does not **have** to be recursive.)

7. `blur(image, neighborhood_size)` – Blur the image by replacing each pixel with the average of itself and its neighboring pixels. If there aren't enough neighboring pixels for some pixel  $x$  (pixels on the edges of the image), you should just use  $x$  instead of the missing neighbor.

8. `sepia(image, sepiaAmount)` – Write a function that applies a sepia effect, which raises the red and green channels, and lowers the blue. In particular it adds  $2 * \text{sepiaAmount}$  to the red, adds  $\text{sepiaAmount}$  to green, and subtracts  $\text{sepiaAmount}$  from blue. 20 is a good value for `sepiaAmount`.

9. `fairey(image)` – Write a function that applies an effect similar to Shepard Fairey's iconic Obama "HOPE" poster. Each pixel is colored one of four colors depending upon the sum of its RGB values. It assigns roughly equal intervals for each of the four colors.

RGB Sum	Color
0 – 181	darkBlue (0, 51, 76)
182 – 363	red (217, 26, 33)
364 – 545	lightBlue (112, 150, 158)
545 – 765	yellow (252, 227, 166)
